### Missing Proofs, lecture 6. July 8<sup>th</sup>.

**Claim:** In any graph, there is an odd number of vertices with an odd degree.

**Proof:** The total degree is  $2|E|$ . The vertices with an even degree contribute together to the total degree  $2k$  (for some integer  $2k$ ). Therefore, the vertices of odd degree contribute  $2(|E| - k)$  to the total degree, which is an even number. Given that the sum of  $x$  odd integers is even, it must be that  $x$  is even.

**Lemma 1:**  $G$  has a postman cycle of length  $k$  if and only if  $G$  has an Eulerian extension of total edge weight  $k$ .

**Proof:** a. Suppose  $G$  has a postman cycle  $W$  of length  $k$ . Construct an extension  $G^*$  of  $G$  by replacing each edge of  $G$  by  $p(e)$  parallel edges, where  $p(e)$  is the number of times  $e$  is contained in  $W$ . Then  $G^*$  is Eulerian since  $W$  is an Euler tour in  $G^*$ . Furthermore,  $\text{length}(W) = w(G^*)$ .

b. Suppose  $G$  has an Eulerian extension  $G^*$  of weight  $k$ . Let  $R$  be an Euler tour of  $G^*$ . Then  $R$  corresponds to a postman walk  $W$  for  $G$  with  $\text{length}(W) = w(G^*)$ . Thus,  $G$  has a postman walk of length  $k$ .

**Missing argument in the proof of Edmonds-Johnson Algorithm:** We show that the paths corresponding to the min-matching are edge disjoint. Assume by contradiction that there are two paths  $p_1 = a \text{---} b$  and  $p_2 = c \text{---} d$  with a common edge  $e = (u, v)$ . That is,  $p_1 = a \text{---} u \text{---} v \text{---} b$  and  $p_2 = c \text{---} u \text{---} v \text{---} d$ , then by replacing  $p_1$  and  $p_2$  by  $a \text{---} u \text{---} c$  and  $b \text{---} v \text{---} d$  we get a cheaper matching of the odd-degree vertices (cheaper by  $2w(e)$ ), contradicting the optimality of the min-cost matching.

**Conclusion:** Every edge appears at most once in the extension and step 4 produces a valid min-cost Eulerian extension of  $G$ .

**The analysis of 3/2-approximation for TSP is tight:** The graph in the figure presents an instance of TSP. It has  $2n+1$  nodes, all solid edges have length 1, all dashed edges have weight  $1+\epsilon$ .

The only MST consists of all solid lines, it has length  $2n$ . No shortcuts are needed. The first and last nodes have odd degree. The edge connecting them has length  $(1+\epsilon)n$ . All together, the TSP path detected by the algorithm has length  $\sim 3n$ .

An optimal tour consists of the dashed edges + the leftmost and rightmost edges. Its length is  $(2n-1)(1+\epsilon) + 2 \sim 2n$
